

SENDKIT DOCS

Dedicated IPs and isolated infrastructure, explained

Think of a sending platform as a house. On most cold email platforms, you get a room in a house shared with hundreds of other senders, and you have no idea who else is living there.

Why your roommates are your problem

Inbox providers score IP reputation at the IP level, not the individual-sender level. If enough senders on a shared IP get marked as spam, the whole IP's reputation drops, and every other sender on it, including you, starts landing in spam too, regardless of how clean your own sending is. You can warm up properly, write good copy, and keep bounce rates low, and still get dragged down by a stranger sharing your infrastructure. That is the core risk of shared IPs: your deliverability is only as good as the worst sender on your platform.

A dedicated IP flips this. It is your own house. Nobody else sends from your IP, your headers, or your server, so your reputation is entirely a function of your own behavior.

Deliverability runs on four reputations, not one

Every send is scored on IP reputation, domain reputation, mailbox reputation, and copy reputation, all at once. A perfectly warmed mailbox on a burned IP still lands in spam; great copy from an unwarmed mailbox still lands in spam. There is no single lever, which is why isolating the infrastructure variable matters: it removes the one reputation risk that is entirely outside your control on a shared platform. Nobody, including SendKit, can guarantee primary inbox placement, since every reputation shifts constantly and inbox providers change filters without notice. What a platform can control is the variables it owns: isolated infrastructure, real warm-up, and honest reporting.

Verify it yourself

- 01 Open any email you have received, or a test send, and find "show original" or "view source" in your email client.
- 02 Copy the raw header text and paste it into MX Toolbox's header analyzer.
- 03 Check the sending IP and whether it is uniquely tied to one sender or shared across many. Headers do not lie about which infrastructure sent a message, dedicated or quietly shared behind marketing language.

WHY THIS WORKS ON SENDKIT

Every SendKit customer gets a fully isolated dedicated IP and server, unique headers included, on every plan from Essential up. Run the MX Toolbox check on your own SendKit sends and you will see exactly one sender behind that IP: you. Health scores are real too: a mailbox will not show full health on day one, only once consistent inbox landing is actually verified.

See your own IP in the header analysis

Book a demo and run the MX Toolbox header check live on a SendKit send to see your isolated IP for yourself.
