

SENDKIT DOCS

Import and validate your leads

A sequence with no leads does not send. Before you write anything, get your list into SendKit and let it validate the addresses.

Three ways to bring leads in

01 CSV upload

The most common route. Upload your file, map the columns, email, name, company, whatever you have, done.

02 CRM sync

Connect HubSpot, Pipedrive, Salesforce, Zoho, or GHL and pull leads straight from there.

03 API

Push leads in programmatically if you are generating or scraping them elsewhere.

Don't have a list yet? SendKit's lead database holds over 400 million contacts you can search and pull from directly, no separate tool needed.

Validation runs automatically

Every lead you import gets email validation at no extra cost, on every plan, from the \$99 plan up. This catches addresses that will bounce before you ever send to them. When bounce rates start climbing, that is the sign to revalidate the list rather than push through.

SEG detection on import

Secure email gateways such as Proofpoint, Barracuda, Mimecast, or Microsoft Defender sit in front of some inboxes and filter mail before it reaches an inbox. Cold email to a SEG-protected address behaves differently, often getting caught regardless of sending reputation. SendKit tags these leads automatically during import, so you can see which of your contacts sit behind one. Unless your entire ICP is enterprise, the simplest move is to skip sending to SEG-protected leads and focus on the leads without that extra filter in the way.

Filter before you send

Once leads are in, filter by verified or unverified, by SEG provider, by contacted or bounced status, or by mail provider. This builds a clean sending list instead of blasting everyone at once.

WHY THIS WORKS ON SENDKIT

Free validation and SEG detection on every plan mean you are not paying extra just to find out which leads are worth sending to. That is baked into signup, not an upsell.

Run validation on your next list

Import your next CSV or CRM sync, then filter by verified status and SEG tag before you build a sending list.
