

# Prove your placement before you scale

An inbox placement test shows exactly where your emails land, primary inbox, promotions, or spam, per mailbox, instead of leaving you to infer it from reply counts.

## What a placement test shows

The test sends real emails through your mailboxes on the same infrastructure your campaigns use, so the result reflects your actual setup rather than a simulated inbox. It is included in your subscription at no extra cost. Test sends count against your normal sending limits, so run it to answer a real question, not as a constant background check. Spam placement testing runs on Saturdays and Sundays, so do not expect same-day results for that part midweek.

## When to run one

### Before scaling

Prove placement before adding volume or pointing new mailboxes at a live campaign.

### After a change

Paused a mailbox, revalidated a list, or extended warm-up? Re-run to confirm the change moved the number.

### When replies dip

A campaign that used to convert has gone quiet. Rule out placement first.

### When one mailbox looks off

The test reads per mailbox, so a single odd mailbox is exactly its job.

## How to read the results

| Pattern                                 | What it means                                           | What to do                                                                            |
|-----------------------------------------|---------------------------------------------------------|---------------------------------------------------------------------------------------|
| Most or all mailboxes land in primary   | Sending infrastructure is healthy right now             | Scale as planned; keep a weekly health check                                          |
| A few mailboxes in spam, the rest clean | A mailbox-specific problem                              | Check its health score and recent pattern; disable cold sending, keep warm-up running |
| Most or all mailboxes in spam           | A broader issue: recipient mix or list, not one mailbox | Revalidate the list and review the recipient mix before sending more                  |

## Acting on it

### 01 Filter mailboxes to health above 95

Weekly if you run any real volume. Investigate anything below the line before it drags a campaign down.

### 02 Check cold versus warm-up replies

Email Insights splits reply activity by cold versus warm-up. A mailbox can look busy on total replies while its cold replies are quiet.

### 03 Disable sending on consistent underperformers

Pause cold sending while warm-up keeps running. Run well, a mailbox lasts 6 to 12 months; mishandled, it burns out in weeks.

### 04 Treat every result as a snapshot, not a verdict

Change something, then re-run the test to see whether the number actually moved.

### Run a placement test

Kick one off from your SendKit workspace on the mailboxes behind your next launch, then read the result against the table above before you scale.
